

Python

Programming

Variables & Operations

Dr. Chun-Hsiang Chan
Department of Geography
National Taiwan Normal University

Outlines

- Variables
- Data Types
- Strings
- Booleans
- Operators
- Assignments

Variables

- As a programming language, Python also have some striction during variable declaration.
- In addition, Python is a special programming language that all variables just like chameleon, which I will mention later.
- First of all, the rule of variable names: try the followings,

```
avar = "hello"  
a_var = "hello"  
_var = "hello"  
aVar = "hello"  
var2 = "hello"
```

```
1avar = "hello"  
1a_var = "hello"  
a var = "hello"  
a-Var = "hello"  
a@var2 = "hello"
```

Variables

- Variable name style with multi-word combinations

- **Camel case**

```
aVarEx = 3
```

- **Pascal case**

```
AVarEx = 3
```

- **Snake case**

```
a_var_ex = 3
```

- **Delete a variable**

```
del a_var_ex
```

Variables

- Declare a variable without casting

```
a = 3  
b = 3.7
```

- Declare a variable with casting

```
a = str(3)  
b = float(3.7)
```

- Get data type information

```
print(type(a))  
print(type(b))
```

Variables

- Assign **multiple variables** at one time.

```
a, b, c = 3, 3.5, "master"  
print(a)  
print(b)  
print(c)  
abc = [3, 3.5, "master"]  
a, b, c = abc  
print(a)  
print(b)  
print(c)
```

Variables

- Print the **multiple variables** with **concatenation** or **formation**.

```
a, b, c = "I", "am", "master"  
print(a, b, c)  
print(a + b + c)  
abc = "I am master"  
print(abc)
```

```
d = 10  
e = 20  
print(d+e)
```

```
# add ending symbol  
print(abc, end="@")  
print(abc, end="!")
```

```
# formatting the numbers  
m = 123.456789  
print("{0:.2f}".format(m))  
print("{0:.3f}".format(m))  
print(round(m, 2))
```

Data Types

- In Python, there are several data types: text, numeric, sequence, mapping, set, boolean, binary, and none types.

text type

str

numeric type

int, float, double, complex

sequence type

list, tuple, range

mapping type

dict

set type

set, frozenset

boolean type

bool

binary type

byte, bytearray, memoryview

none type

NoneType

Data Types

```
A = "master"
```

```
A = 20
```

```
A = 20.567
```

```
A = 2j
```

```
A = ["m1", "m2", "m3"]
```

```
A = ("m1", "m2", "m3")
```

```
A = range(10)
```

```
A = {"name": "mike", "wt": 65}
```

```
A = {"m1", "m2", "m3"}
```

str

int

float

complex

list

tuple

range

dict

set

Data Types and Numbers

```
A = frozenset({"m1", "m2", "m3"})
```

frozenset

```
A = True
```

bool

```
A = b"m1"
```

bytes

```
A = bytearray(10)
```

bytearray

```
A = memoryview(bytes(20))
```

memoryview

```
A = None
```

NoneType

- Numbers: Special case

```
x = 3e10 # what is the data type of x? test and run
```

```
y = 3E10 # what is the data type of y? test and run
```

Strings

- String is the most common data type in Python, and we may use different ways for declaring a string.

- **Multiple line string**

```
a = "once upon a time, there was a kingdom ..."  
b = "once upon a time, \nthere was a kingdom ..."  
c = """once upon a time, there was a kingdom  
with a large territory"""
```

- **Indexing a string**

```
a[1], a[:10], a[2:8], a[10:], a[-10:-1], a[-8:]
```

Strings

- In some case, we want to change the format of all strings in one time, for example ...

```
a = "once upon a time, there was a kingdom ..."  
print(a.upper()) # returns the string in upper case  
print(a.lower()) # returns the string in upper case  
print(a.strip()) # returns the string without space from the  
beginning and the end  
print(a.replace("o", "X")) # replaces the specific words  
print(a.split(",")) # split the string by comma
```

Strings

- Speaking of splitting a string, we could concatenate strings together or format a string.

```
a, b, c = "I", "am", "master"  
print(a, b, c)  
print(a + b + c)  
print(a + " " + b + " " + c)  
age = 18  
txt = "Hey, I'm Mike and {} year-old"  
print(txt.format(age)) "
```

Strings

- Speaking of splitting a string, we could concatenate strings together or format a string.

```
age = 3
height = 567
weight = 49.95
txtOrder = "My sister's height and weight are {2} and {0} ,
respectively, while she is {1} year-old."
print(txtOrder.format(weight, age, height))
```

Strings

- How to type in some special characters?

`\'` Single quote

`\\` Backslash

`\n` New line

`\t` Tab

`\b` Backspace

`\ooo` Octal value

`\xhh` Hex value

Strings – Octal and Hex Value

Decimal	Binary	Octal	Hex	ASCII	Decimal	Binary	Octal	Hex	ASCII	Decimal	Binary	Octal	Hex	ASCII	Decimal	Binary	Octal	Hex	ASCII

Strings – Methods

Method	Description
<u>capitalize()</u>	Converts the first character to upper case
<u>casefold()</u>	Converts string into lower case
<u>center()</u>	Returns a centered string
<u>count()</u>	Returns the number of times a specified value occurs in a string
<u>encode()</u>	Returns an encoded version of the string
<u>endswith()</u>	Returns true if the string ends with the specified value
<u>expandtabs()</u>	Sets the tab size of the string
<u>find()</u>	Searches the string for a specified value and returns the position of where it was found
<u>format()</u>	Formats specified values in a string
<u>format_map()</u>	Formats specified values in a string
<u>index()</u>	Searches the string for a specified value and returns the position of where it was found
<u>isalnum()</u>	Returns True if all characters in the string are alphanumeric
<u>isalpha()</u>	Returns True if all characters in the string are in the alphabet
<u>isascii()</u>	Returns True if all characters in the string are ascii characters
<u>isdecimal()</u>	Returns True if all characters in the string are decimals
<u>isdigit()</u>	Returns True if all characters in the string are digits
<u>isidentifier()</u>	Returns True if the string is an identifier
<u>islower()</u>	Returns True if all characters in the string are lower case
<u>isnumeric()</u>	Returns True if all characters in the string are numeric
<u>isprintable()</u>	Returns True if all characters in the string are printable

Source: https://www.w3schools.com/python/python_strings_methods.asp

<u>isspace()</u>	Returns True if all characters in the string are whitespaces
<u>istitle()</u>	Returns True if the string follows the rules of a title
<u>isupper()</u>	Returns True if all characters in the string are upper case
<u>join()</u>	Joins the elements of an iterable to the end of the string
<u>ljust()</u>	Returns a left justified version of the string
<u>lower()</u>	Converts a string into lower case
<u>lstrip()</u>	Returns a left trim version of the string
<u>maketrans()</u>	Returns a translation table to be used in translations
<u>partition()</u>	Returns a tuple where the string is parted into three parts
<u>replace()</u>	Returns a string where a specified value is replaced with a specified value
<u>rfind()</u>	Searches the string for a specified value and returns the last position of where it was found
<u>rindex()</u>	Searches the string for a specified value and returns the last position of where it was found
<u>rjust()</u>	Returns a right justified version of the string
<u>rpartition()</u>	Returns a tuple where the string is parted into three parts
<u>rsplit()</u>	Splits the string at the specified separator, and returns a list
<u>rstrip()</u>	Returns a right trim version of the string
<u>split()</u>	Splits the string at the specified separator, and returns a list
<u>splitlines()</u>	Splits the string at line breaks and returns a list
<u>startswith()</u>	Returns true if the string starts with the specified value
<u>strip()</u>	Returns a trimmed version of the string
<u>swapcase()</u>	Swaps cases, lower case becomes upper case and vice versa
<u>title()</u>	Converts the first character of each word to upper case
<u>translate()</u>	Returns a translated string
<u>upper()</u>	Converts a string into upper case
<u>zfill()</u>	Fills the string with a specified number of 0 values at the beginning

Booleans

- In Python, there are two boolean values: **True** and **False**.

```
# basic
print(1>2)
print(1>=2)
print(2==2)
print(1<2)
# try some specials
print(bool(12))
print(bool("am"))
```

Operators

- For sure, you may do some mathematic calculation.

Operator	Name	Example
+	addition	$x + y$
-	subtraction	$x - y$
*	multiplication	$x * y$
/	division	x / y
%	modulus	$x \% y$
**	exponentiation	$x ** y$
//	floor division	$x // y$

Source: https://www.w3schools.com/python/python_operators.asp

Operators

- There are some fantastic operators.

Operator	Example	Same as
=	x = 5	x = 5
+=	x += 3	x = x + 3
-=	x -= 3	x = x - 3
*=	x *= 3	x = x * 3
/=	x /= 3	x = x / 3
%=	x %= 3	x = x % 3
//=	x //= 3	x = x // 3
**=	x **= 3	x = x ** 3
&=	x &= 3	x = x & 3
=	x = 3	x = x 3
^=	x ^= 3	x = x ^ 3
>>=	x >>= 3	x = x >> 3
<<=	x <<= 3	x = x << 3

Assignment #01

- In Taiwan, our government adopts the Richter Scale to quantify a seismic event's magnitude. However, news reporters prefer to conduct the number of TNT bombs equivalent to seismic energy. Here are the energy equations.

$$\log_{10} E = 4.4 + 1.5 \times M_L$$
$$1 \text{ ton of TNT} = 4.184 \times 10^9 J$$

- In addition, the equivalence Hiroshima-bomb is 12.5 *kT* TNT.
- Design a function that the user may give a M_L value, and it will return the number of Hiroshima-bombs.

Assignment #01

Format

```
def earthquake2bomb(ML):  
    # annotation  
    ...  
    ...  
    ...  
    return num_bomb
```

- You need to notice the precision issue.
- The return value should be an integer.
- You may use a function called “round” to obtain an integer number.

The End

Thank you for your attention!
